(57) **ABSTRACT**

Certain aspects and features of the present invention are directed to a supercapacitor device that can be disposed in a wellbore through a fluid-producing formation. The supercapacitor device can include a body that can be disposed in the wellbore, a supercapacitor disposed in the body, at least two terminals disposed at least partially outside the body, and an actuation mechanism. The supercapacitor stores energy. The terminals can be electrically connected with the supercapacitor. An electrical connection between the supercapacitor and the terminals can cause the energy to be discharged from the supercapacitor in response to a conductive material providing an electrical path between the at least two terminals. The actuation mechanism can selectively prevent a deployment of the supercapacitor device in the wellbore from causing a discharge of the energy from the supercapacitor.

DOWNHOLE SUPERCAPACITOR DEVICE**CROSS-REFERENCE TO RELATED APPLICATIONS**

This is a divisional of U.S. patent application Ser. No. 14/142,167, filed Dec. 27, 2013, which is a continuation of PCT/US2013/020100, filed Jan. 3, 2013, the entirety of both which are incorporated herein by reference.

TECHNICAL FIELD OF THE INVENTION

The present invention relates generally to devices for deploying tools in a wellbore in a subterranean formation and, more particularly (although not necessarily exclusively), to a downhole device including one or more supercapacitors used to transfer electrical or thermal power to downhole materials in a well system.

BACKGROUND

A well system, such as an oil or gas well for extracting fluids that can include petroleum oil hydrocarbons from a subterranean formation, can include structures or tools that require cutting to prepare the well for the production of petroleum oil hydrocarbons or other production fluids. In one example, an opening can be cut into a vertical section of a tubing string of the well system in order to add a horizontal section to the tubing string. In another example, a tubing string can be perforated by a group of perforating guns to allow the flow of fluid into the tubing string from the formation. Downhole structures or tools, such as tubing sections, can be formed from materials that are resistant to high temperature or pressure. Cutting tools deploying in a downhole environment can require a relatively large amount of energy to cut the downhole structures or tools. For example, a welding tool deployed in a well system may require a relatively cumbersome energy storage system or an additional power line to be deployed into the well system with the welding system.

It is desirable to provide a compact downhole tools for applying a high amount of energy to downhole tools and structures.

SUMMARY

In one aspect, a supercapacitor device is provided that can be disposed in a wellbore through a fluid-producing formation. The supercapacitor device can include a body that can be disposed in the wellbore, at least one supercapacitor disposed in the body, at least two terminals disposed at least partially outside the body, and an actuation mechanism. The supercapacitor can store energy. The at least two terminals can be electrically connected with the supercapacitor. An electrical connection between the supercapacitor and the at least two terminals can cause the energy to be discharged from the supercapacitor in response to a conductive material providing an electrical path between the at least two terminals. The actuation mechanism can selectively prevent a deployment of the supercapacitor device in the wellbore from causing a discharge of the energy from the supercapacitor.

In another aspect, a method is provided. The method involves deploying a supercapacitor device in a wellbore through a fluid-producing formation. The supercapacitor device includes at least one supercapacitor configured to store energy, at least two terminals, and an actuation mechanism. The actuation mechanism can selectively prevent a deployment

2

ment of the supercapacitor device in the wellbore from causing a discharge of the energy from the supercapacitor. The method also involves positioning the supercapacitor device such that the at least two terminals are in contact with a conductive material in the wellbore. The method also involves discharging the energy from the supercapacitor by actuating the actuation mechanism.

These illustrative aspects and features are mentioned not to limit or define the invention, but to provide examples to aid understanding of the inventive concepts disclosed in this application. Other aspects, advantages, and features of the present invention will become apparent after review of the entire application.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic illustration of a well system in which a supercapacitor device can be disposed according to one aspect of the present invention.

FIG. 2 is a cross-sectional view of a supercapacitor device that can be deployed in a well system according to one aspect of the present invention.

FIG. 3 is a cross-sectional view of a supercapacitor device melting a conductive material according to one aspect of the present invention.

FIG. 4 is a cross-sectional view of a supercapacitor device deployed in a well system as a retrieval tool according to one aspect of the present invention.

FIG. 5 is a cross-sectional view of a supercapacitor device including an actuation mechanism for selectively displacing a non-conductive material to prevent a prematurely discharging energy according to one aspect of the present invention.

FIG. 6 is a cross-sectional view of a supercapacitor device including an actuation mechanism displacing the non-conductive material to allow a discharge of energy from the supercapacitor device according to one aspect of the present invention.

FIG. 7 is a cross-sectional view of a supercapacitor device including a spring-loaded actuation mechanism for selectively preventing at least one terminal from being electrically connected to the supercapacitor according to one aspect of the present invention.

FIG. 8 is a cross-sectional view of a supercapacitor device including a spring-loaded actuation mechanism selectively allowing terminals to be electrically connected to a supercapacitor according to one aspect of the present invention.

FIG. 9 is a cross-sectional view of a supercapacitor device including an actuation mechanism with a compressible fluid for selectively preventing at least one terminal from being electrically connected to the supercapacitor according to one aspect of the present invention.

FIG. 10 is a cross-sectional view of a supercapacitor device including an actuation mechanism with a compressible fluid selectively allowing terminals to be electrically connected to a supercapacitor according to one aspect of the present invention.

FIG. 11 is a cross-sectional view of a supercapacitor device having an actuation mechanism that includes a motor for selectively allowing at least one terminal from being electrically connected to the supercapacitor according to one aspect of the present invention.

FIG. 12 is a cross-sectional view of a supercapacitor device having an actuation mechanism that includes a motor allowing the terminals of the supercapacitor device to be electrically connected to a supercapacitor according to one aspect of the present invention.

3

FIG. 13 is a cross-sectional view of a supercapacitor device having an actuation mechanism that includes a motor for selectively actuating a relay to electrically connect the terminals and the supercapacitor according to one aspect of the present invention.

FIG. 14 is a cross-sectional view of a supercapacitor device having an actuation mechanism that includes a motor for actuating a relay to electrically connect the terminals and the supercapacitor according to one aspect of the present invention.

FIG. 15 is a cross-sectional view depicting multiple supercapacitors electrically connected in series with one another according to one aspect of the present invention.

FIG. 16 is a cross-sectional view depicting multiple supercapacitors electrically connected in parallel with one another according to one aspect of the present invention.

FIG. 17 is a cross-sectional view depicting a supercapacitor device being deployed into a well system according to one aspect of the present invention.

FIG. 18 is a cross-sectional view depicting a supercapacitor device positioned in proximity to an object in a well system according to one aspect of the present invention.

FIG. 19 is a cross-sectional view depicting a supercapacitor device being positioned in contact with a conductive material of an object in a well system according to one aspect of the present invention.

FIG. 20 is a perspective view of a section of a tubing string that can be severed by a supercapacitor device contacting a severing tool according to one aspect of the present invention.

FIG. 21 is a perspective view of a supercapacitor device contacting a severing tool to sever a tubing string section according to one aspect of the present invention.

FIG. 22 is a perspective view of a section of the tubing string severed using a supercapacitor device according to one aspect of the present invention.

FIG. 23 is a perspective view of a supercapacitor cutting device for cutting a section of a tubing string according to one aspect of the present invention.

FIG. 24 is a perspective view of the supercapacitor cutting device cutting the section of the tubing string according to one aspect of the present invention.

FIG. 25 is a cross-sectional view of a battery disposed in a tubing string that can be recharged by a supercapacitor device according to one aspect of the present invention.

FIG. 26 is a cross-sectional view of a supercapacitor device recharging a battery according to one aspect of the present invention.

FIG. 27 is a cross-sectional view of a tool string including a firing head assembly in which a supercapacitor device can be disposed according to one aspect of the present invention.

FIG. 28 is a cross-sectional view of firing head assembly including a supercapacitor device according to one aspect of the present invention.

DETAILED DESCRIPTION

Certain aspects and features of the present invention are directed to a supercapacitor device configured to be deployed downhole in a well system. The supercapacitor device can include at least one supercapacitor (also known as an electric double-layer capacitor, electrochemical double layer capacitor, or ultracapacitor) with a relatively high energy density for storing electrical or thermal power that can be released and applied to downhole materials, structures, tools, etc. The stored energy can be rapidly discharged by positioning the supercapacitor in contact with a conductive material in a

4

wellbore, such as a metallic object. For example, the energy can be discharged by short-circuiting a supercapacitor using the conductive material.

The superconductor device can provide a compact energy storage solution for deployment in a downhole environment. The supercapacitor device can be used as a downhole welding device to weld, cut, or join two pieces of conductive material. The supercapacitor device can also be used as a downhole retrieval device that can be fused to an object downhole.

The supercapacitor device can also include an actuation mechanism for preventing a premature discharge of the supercapacitor caused by a deployment of the supercapacitor device in the wellbore from causing. For example, the actuation mechanism can include a non-conductive material that wholly or partially surrounds the terminals of the supercapacitor device. The non-conductive material can prevent an electrical path from being formed between the terminals. The actuation mechanism can also include a mechanism for displacing the non-conductive material after the supercapacitor is deployed to a desired position in the wellbore.

The supercapacitor device can be used for any suitable application involving the discharge of heat energy or electrical current. In some aspects, the supercapacitor device can be used as a retrieval tool for retrieving an object from a wellbore by fusing the object to the supercapacitor device via a conductive material melted by discharging the supercapacitor. In other aspects, the supercapacitor device can be used to cut a perforation in a vertical section of the tubing string to allow for drilling in a horizontal direction or to sever a section of the tubing string for retrieval. In another non-limiting example, the supercapacitor device can be used to melt or cut a perforation into a disc, thereby allowing rupture discs configured to withstand relatively low pressure (such as rubber or plastic rupture discs) to be replaced with a metal disc configured to withstand higher pressures at greater depths in the well system. In other aspects, the supercapacitor device can be used to charge a downhole battery. In other aspects, the supercapacitor device can be used to detonate a detonating material of a gun assembly for perforating a tubing string.

These illustrative examples are given to introduce the reader to the general subject matter discussed here and are not intended to limit the scope of the disclosed concepts. The following sections describe various additional aspects and examples with reference to the drawings in which like numerals indicate like elements, and directional descriptions are used to describe the illustrative aspects. The following sections use directional descriptions such as "above," "below," "upper," "lower," "upward," "downward," "left," "right," "uphole," "downhole," etc. in relation to the illustrative aspects as they are depicted in the figures, the upward direction being toward the top of the corresponding figure and the downward direction being toward the bottom of the corresponding figure, the uphole direction being toward the surface of the well and the downhole direction being toward the toe of the well. Like the illustrative aspects, the numerals and directional descriptions included in the following sections should not be used to limit the present invention.

FIG. 1 schematically depicts a well system 100 in which a supercapacitor device can be deployed. The well system 100 includes a bore that is a wellbore 102 extending through various earth strata. The wellbore 102 has a substantially vertical section 104 and a substantially horizontal section 106. The substantially vertical section 104 and the substantially horizontal section 106 may include a casing string 108 cemented at an upper portion of the substantially vertical section 104. In some aspects, a liner can be disposed within the wellbore 102. A liner can be a casing string that does not

5

extend to the top of the wellbore **102** and is anchored or suspended from inside the bottom of a previous casing string. The substantially horizontal section **106** extends through a hydrocarbon bearing subterranean formation **110**.

A tubing string **112** extends from the surface within wellbore **102**. The tubing string **112** can provide a conduit for formation fluids, such as production fluids produced from the subterranean formation **110**, to travel from the substantially horizontal section **106** to the surface. Pressure from a bore in a subterranean formation can cause formation fluids, such as gas or petroleum, to flow to the surface. The rate of fluid flow can be controlled using one or more inflow control devices.

The supercapacitor device **114**, depicted as a functional block in FIG. 1, can be positioned in the tubing string **112** at a vertical section **104** or at a horizontal section **106**. In some aspects, a supercapacitor device can be deployed in simpler wellbores, such as wellbores having only a substantially vertical section.

FIG. 2 is a cross-sectional view of a supercapacitor device **114** that can be deployed in a well system **100**. The supercapacitor device **114** can include a supercapacitor **204**, terminals **206a**, **206b**, and a body **208**. The supercapacitor **204** can be disposed in the body **208**. The terminals **206a**, **206b** can be electrically connected to the supercapacitor **204**.

The supercapacitor **204** can be discharged by positioning the supercapacitor device **114** such that the terminals **206a**, **206b** contact a conductive material **210**. The terminals **206a**, **206b** contacting the conductive material **210** can form an electrical path between the terminals **206a**, **206b**. The electrical path between the terminals **206a**, **206b** and the electrical connection between the terminals **206a**, **206b** and the supercapacitor **204** can discharge energy stored in the supercapacitor **204**.

The supercapacitor device **114** can be discharged via any suitable conductive material **210**. A non-limiting example of a suitable conductive material is a metal. The conductive material **210** can be a part of any tool, structure, or other object in the well system.

In some aspects, discharging the supercapacitor **204** can cause sufficient heat to be generated in, or transferred to, the conductive material **210** such that the conductive material **210** melts. For example, FIG. 3 is a cross-sectional view of a supercapacitor device **114** melting a conductive material **210**. The conductive material **210** can melt and separate into the conductive materials **210a**, **210b**.

In some aspects, the supercapacitor device **114** can be used as a retrieval tool in a well system **100**. For example, FIG. 4 is a cross-sectional view of supercapacitor device **114** that is deployed in a well system **100** as a retrieval tool. The supercapacitor device **114** can be deployed into a well system **100** via any suitable retrieval mechanism **302**, such as (but not limited to) a control line or a wireline system. The supercapacitor device **114** can melt conductive material **210a**, **210b** that is in contact with an object **304** in the well system. The conductive material **210a**, **210b** can solidify after melting, thereby fusing the object **304** to the supercapacitor device **114** via the conductive material **210a**, **210b**. The supercapacitor device **114** coupled to the object **304** can be retrieved via the retrieval mechanism **302**.

In some aspects, the conductive material **210a**, **210b** can be a part of the object **304**. In other aspects, a conductive material **210** can be deployed with the supercapacitor device **114**. For example, a downhole tool may include a conductive material that can be melted by energy discharged from the supercapacitor device **114**. The conductive material **210** can be melted by discharging the supercapacitor device **114** after

6

positioning the supercapacitor device **114** such that the conductive material is in contact with the object **304**.

A supercapacitor device can include any suitable actuation mechanism for preventing a premature discharge of energy from the supercapacitor **204** during deployment into a wellbore. For example, FIGS. 5-6 are cross-sectional views of a supercapacitor device **114'** that includes an actuation mechanism **404** for selectively displacing a non-conductive material **402** that prevents a premature discharge of energy from the supercapacitor device **114'**.

As depicted in FIG. 5, the supercapacitor device **114'** can include the non-conductive material **402** and an actuation mechanism **404**. The non-conductive material **402** can wholly or partially surround the terminals **206a**, **206b**. The non-conductive material **402** can be any suitable non-conductive material for preventing an electrical path from being formed between the terminals **206a**, **206b**. Non-limiting examples of a suitable non-conductive material can include rubber, plastic, glass, a dielectric fluid enclosed in a container, etc. The non-conductive material **402** can prevent a premature discharge of the supercapacitor device **114'** as the supercapacitor device **114'** is deployed downhole into the well system **100**.

The non-conductive material **402** can be displaced after the supercapacitor device **114'** is deployed to a desired position in the wellbore, such as a position in proximity to an object to be welded, cut, retrieved, or otherwise manipulated using the supercapacitor device **114'**. The actuation mechanism **404** can apply a force to the non-conductive material **402**. The force can displace the non-conductive material **402**. For example, as depicted in FIG. 6, the actuation mechanism **404** can be extended in a direction away from the body **208**. Extending the actuation mechanism **404** can apply a force to the non-conductive material **402** in the direction away from the body **208**. Displacing the non-conductive material **402** can allow an electrical path to be formed between the terminals **206a**, **206b**.

The actuation mechanism **404** can be triggered via any suitable mechanism, such as an electrical or mechanical switch. The triggering of the actuation mechanism **404** can be provided via any suitable mechanism, such as (but not limited to) a control line or communication signal from a control unit at the surface.

Although FIGS. 5-6 depict an actuation mechanism **404** contacting one end of a non-conductive material **402** to displace a single non-conductive material **402**, other implementations are possible. In additional or alternative aspects, a cap formed from a non-conductive material can be positioned over one or both of the terminals **206a**, **206b**. Each cap can be displaced via a respective actuation mechanism configured to apply a force to the cap.

Although FIGS. 5-6 depict an actuation mechanism **404** applying a force via contact with the non-conductive material **402**, other implementations are possible. In additional or alternative aspects, an actuation mechanism can include a mechanism configured to communicate pressure to the non-conductive material **402**, thereby displacing the non-conductive material **402**. For example, the actuation mechanism can generate the force by mixing two chemicals to generate pressure. The actuation mechanism can be adapted to communicate the pressure to the non-conductive material **402**. Communicating the pressure to the non-conductive material **402** can displace the non-conductive material **402**.

In additional or alternative aspects, an actuation mechanism can prevent a premature discharge of the supercapacitor **204** by selectively preventing at least one terminal from being electrically connected to the supercapacitor **204**. FIGS. 7-8

are cross-sectional views of a supercapacitor device **114"** including an actuation mechanism for selectively preventing at least one terminal from being electrically connected to the supercapacitor **204**. As depicted in FIG. 7, the supercapacitor device **114"** can include retaining structures **502a, 502b** coupled to or otherwise in contact with the terminals **206a, 206b**. The retaining structures **502a, 502b** can retain the terminals **206a, 206b** in a position such that the terminals **206a, 206b** are electrically disconnected from the supercapacitor **204**, thereby preventing a discharge of the supercapacitor **204**.

Applying force to the terminals **206a, 206b** in the direction of the body **208** can cause the terminals **206a, 206b** to move toward the body **208**. The terminals **206a, 206b** moving toward the body **208** can electrically couple the terminals **206a, 206b** to the supercapacitor **204**, thereby causing the supercapacitor **204** to discharge stored energy.

In some aspects, the retaining structures **502a, 502b** can include compressible actuation mechanisms. The compressible actuation mechanisms can be compressed by the application of force to the terminals **206a, 206b** in the direction of the body **208**, thereby forming an electrical connection between the terminals **206a, 206b** and the supercapacitor **204**.

A compressible actuation mechanism can include any device, structure, or group of devices and structures that can store mechanical energy that can cause a force to be applied in a direction opposite to a compressing force. One non-limiting example of a compressible actuation mechanism is a device that includes a compression spring adapted to apply a force in a direction away from the body **208**, as depicted in FIGS. 7-8. Another non-limiting example of a compressible actuation mechanism is a device that includes a metal band or other structure adapted to apply a force in a direction away from the body **208**.

Another non-limiting example of a compressible actuation mechanism is a chamber or other structure formed from a flexible material and having a compressible fluid contained in the chamber, as depicted in FIGS. 9-10. The supercapacitor device **114"** can include containers **504a, 504b**. Compressible fluids **506a, 506b** can respectively be stored within inner volumes of the containers **504a, 504b**. The containers **504a, 504b** can be formed from any flexible material suitable for storing the compressible fluids **506a, 506b** and for being deployed in the wellbore **102**. Each of the compressible fluids **506a, 506b** can provide a force to be applied to inner walls of the containers **504a, 504b**. The force applied to the inner walls of the containers **504a, 504b** can cause forces to be applied to the terminals **206a, 206b** in directions away from the body **208**. The application of force to the terminals **206a, 206b** in a direction away from the body **208** can cause one or more of the terminals **206a, 206b** to be electrically disconnected from the supercapacitor **204**, as depicted in FIG. 9. The compressible fluids **506a, 506b** can be compressed by an application of force to the terminals **206a, 206b** in the direction of the compressible fluids **506a, 506b**, as indicated by the downward arrow in FIG. 10. Compressing the compressible fluids **506a, 506b** can cause the terminals **206a, 206b** to be electrically connected to the supercapacitor **204**.

Although FIGS. 7-10 depict each of the terminals **206a, 206b** in a position that is electrically disconnected from the supercapacitor **204**, other implementations are possible. In additional or alternative aspects, a single one of the terminals **206a, 206b** can be positioned such that an electrical connection is not formed between the terminals **206a, 206b** and the supercapacitor **204**.

In additional or alternative aspects, the supercapacitor device can be actuated by a motor configured to electrically

connect the terminals **206a, 206b** and the supercapacitor **204**. For example, FIGS. 11-14 are cross-sectional views of a supercapacitor device **114"** that can be actuated by a motor **510** controlled by a control device **508**. For simplicity, FIGS. 11-14 depict the control device **508** and the motor **510** as functional blocks.

The control device **508** can be any electrical device suitable for activating the motor **510**. Prior to activation of the motor **510**, one or more of the terminals **206a, 206b** can be electrically disconnected from the supercapacitor **204**, as depicted in FIG. 11. Activating the motor **510** can cause one or more of the disconnected terminals **206a, 206b** to be electrically connected to the supercapacitor **204**. In one non-limiting example, the motor can change the position of one or more of the terminals **206a, 206b** such that both terminals are electrically connected to the supercapacitor **204**, as depicted by the downward arrow in FIG. 12. In another non-limiting example, a motor **510** or other suitable device can actuate one or more relays such that the one or more relays electrically connect one or more of the disconnected terminals **206a, 206b** to the supercapacitor **204**. FIGS. 13-14 are cross-sectional views of a supercapacitor device **114"** that can be actuated by the motor **510** and a relay **512**. The relay **512** can be moved from an open position, as depicted in FIG. 13, to a closed position, as depicted in FIG. 14.

The control device **508** can be actuated by any suitable mechanism. In some aspects, a control signal for actuating the control device **508** can be communicated to the control device via wired or wireless communication. In other aspects, the control device **508** can be actuated by a force sensor, accelerometer, or other device can detect a sudden force or by measure the depth of the supercapacitor device **114"**. The control device **508** can activate the motor **510** in response to the force sensor or other device detecting that the supercapacitor device **114"** is at a position in the wellbore **102** that exceeds a threshold depth. In other aspects, the control device **508** can be actuated by a pressure sensor that activates in response to sensing a threshold hydrostatic pressure.

In other aspects, the retaining structures **502a, 502b** can include retaining pins that can be sheared or otherwise broken by the application of force to the terminals **206a, 206b** in the direction of the body **208**. Shearing the retaining pins can allow the terminals **206a, 206b** to be moved toward the body **208**, thereby forming an electrical connection between the terminals **206a, 206b** and the supercapacitor **204**.

Although FIGS. 2-14 depict a supercapacitor device having a single supercapacitor, other implementations are possible. For example, FIG. 15 is a cross-sectional view of a supercapacitor device **114** having multiple supercapacitors **204a, 204b** electrically connected in series with one another. Any number of supercapacitors can be electrically connected in series with one another in a supercapacitor device **114**. Electrically connecting multiple supercapacitors in series with one another can increase the voltage difference across the multiple supercapacitors. The terminals **206a, 206b** can be electrically connected to the supercapacitors **204a, 204b** in series with one another.

In other aspects, multiple supercapacitors can be electrically connected in parallel with one another. FIG. 16 is a cross-sectional view of a supercapacitor device **114** having multiple supercapacitors **204a, 204b** electrically connected in parallel with one another. Any number of supercapacitors can be electrically connected in parallel with one another in a supercapacitor device **114**. Electrically connecting multiple supercapacitors in parallel with one another can increase the electrical current provided by discharging the multiple supercapacitors. The terminals **206a, 206b** can be electrically con-

nected to the supercapacitors **204a**, **204b** electrically connected in parallel with one another.

FIGS. 17-19 are cross-sectional views depicting a supercapacitor device **114** being deployed into a tubing string **112** of the well system **100**. The supercapacitor device can be deployed into the tubing string **112** or another position in a wellbore **102** of the well system **100**, as depicted by the downward arrows in FIGS. 17 and 18. The supercapacitor device **114** can be deployed into the tubing string **112** via any suitable mechanism **302**, such as a wireline or a control line. The supercapacitor device **114** can be positioned in proximity to an object **304** that includes conductive material **210**, as depicted in FIG. 18. The supercapacitor device **114** can be further positioned such that the terminals **206a**, **206b** contact the conductive material **210**, as depicted in FIG. 19.

The energy stored in the supercapacitor device **114** can be discharged by actuating an actuation mechanism. In some aspects, the actuation mechanism can displace a non-conductive material **404** as depicted in FIGS. 5-6 prior to the terminals **206a**, **206b** contacting the conductive material **210**. In other aspects, a force applied by the terminals **206a**, **206b** contacting the conductive material **210** can cause the terminals **206a**, **206b** to form an electrical connection with the supercapacitor **204**, as depicted in FIGS. 7-8.

In additional or alternative aspects, the supercapacitor device **114** can cut, sever, or otherwise perforate pipe such as a section of the tubing string **112**.

For example, FIGS. 20-22 are perspective views of a section of the tubing string **112** that can be severed by a supercapacitor device **114** contacting a severing tool **602**. A tubing section that includes a malfunctioning, tubing-deployed downhole device may be severed from the tubing string **112** and retrieved.

As depicted in FIG. 20, a severing tool **602** can circumferentially surround a section of the tubing string **112**. The severing tool **602** can be formed from any suitable conductive material. The supercapacitor device **114** can be positioned such that the supercapacitor device **114** contacts the severing tool **602**, as depicted by the downward arrow in FIG. 21. The supercapacitor device **114** contacting the severing tool **602** can cause the supercapacitor **204** to discharge. Discharging the supercapacitor **204** can cause electrical current to flow through the severing tool **602**. The electrical current flowing through the severing tool **602** can cause heat to be transferred to the tubing string **112** via the severing tool **602**. The heat can be sufficient to cause the tubing string to sever into a tubing section **112a** and a tubing section **112b**, as depicted in FIG. 22.

In some aspects, the severing tool **602** can be formed from a conductive material with a higher melting temperature than the material forming the tubing string **112**. The severing tool **602** can thus transfer heat to the tubing string **112** without melting. In other aspects, the severing tool **602** can be formed from a conductive material with a melting temperature equal to the melting temperature of the material forming the tubing string **112**. The severing tool **602** can melt in the process of transferring heat to the tubing string **112**.

In another example, the supercapacitor device can be used to perforate or otherwise cut a hole in a section of the tubing string **112**. FIGS. 23-24 are perspective views of a section of the tubing string **112** that can be cut by a supercapacitor cutting device **702**. As depicted in FIG. 23, the supercapacitor cutting device **702** can include a supercapacitor device **114** having a cutting structure **704** electrical coupled to the terminals **206a**, **206b**. The supercapacitor cutting device **702** can be positioned such that the cutting structure **704** contacts a section of the tubing string **112**, as depicted by the rightward

arrow in FIG. 24. The cutting structure **704** contacting the section of the tubing string **112** can apply a force to the terminals **206a**, **206b** in the direction of the body **208** as described above with respect to FIGS. 7-8, thereby causing the supercapacitor device **114** to discharge. Discharging the supercapacitor device **114** can cause electrical current to flow through the cutting structure **704**. The electrical current flowing through the cutting structure **704** that is in contact with the tubing string **112** can cause heat to be transferred to the tubing string **112**. The heat transferred to the tubing string **112** can be sufficient to cut an opening in the tubing string **112** in the shape of the cutting structure **704**.

The cutting structure **704** can be formed from any suitable conductive material. In some aspects, the conductive material of the cutting structure **704** can have a melting point higher than that of the material from which the tubing string **112** is formed, such that the cutting structure **704** can transfer heat to the tubing string **112** without melting the cutting structure **704**. In other aspects, the cutting structure **704** can be melted by transferring heat to the tubing string **112**.

In additional or alternative aspects, the supercapacitor device **114** can be used to charge or recharge an electrical tool downhole. FIGS. 25-26 are cross-sectional views of a battery **802** disposed in the tubing string **112** that can be recharged by a supercapacitor device **114**. The battery **802** can include terminals **804a**, **804b**. The terminals **804a**, **804b** can be adapted to form an electrical connection with the terminals **206a**, **206b** of the supercapacitor device **114**. As depicted in FIG. 25, the supercapacitor device **114** can be deployed into the tubing string **112** via a retrieval mechanism **302** or other suitable mechanism. The supercapacitor device **114** can be positioned such that the terminals **206a**, **206b** form an electrical connection with the terminals **804a**, **804b**, as depicted by the rightward arrow in FIG. 26. The supercapacitor **204** of the supercapacitor device **114** can be discharged as the terminals **206a**, **206b** are electrically connected with the terminals **804a**, **804b**. Discharging the supercapacitor device **114** can cause an electrical current to flow from the supercapacitor device **114** to the battery **802** via the terminals **804a**, **804b**. The electrical current flowing into the battery **802** via the terminals **804a**, **804b** can charge the battery **802**.

In additional or alternative aspects, the supercapacitor device **114** can be used to activate one or more perforating guns used to perforate a pipe in a well system **100**. FIG. 27 is a cross-sectional view of a tool string **901** including a firing head assembly **902** in which a supercapacitor device **114** can be disposed. The tool string **901** can include the firing head assembly **902** and a gun assembly **904**. The gun assembly **904** can be a device, such as one or more perforating guns, for perforating the tubing string **112** in preparation for production of fluid from the formation **110**.

FIG. 28 is a cross-sectional view of an example firing head assembly **902** that includes the supercapacitor device **114** according to one aspect. The firing head assembly **902** can include a detonating cap **906** in contact with a detonating material **908**. The detonating material **908** can be any substance adapted to generate or otherwise provide an explosive force in response to the transfer of heat to the detonating material **908** or the flow of electrical current through the detonating material **908**. The detonating cap **906** can be a conductive material. The supercapacitor device **114** can be discharged by contact with the detonating cap **906**. Discharging the supercapacitor device **114** can cause electrical current to flow through and/or heat to be transferred to the detonating material **908** via the detonating cap **906**. Electrical current flowing through and/or heat being transferred to the detonating material **908** can cause the detonating material **908** to

11

detonate. Detonating the detonating material **908** can cause the gun assembly **904** to perforate the casing string **108** or a liner disposed in the wellbore **102**, thereby allowing the flow of fluid from the formation **110** into the tubing string **112**.

The foregoing description of the aspects, including illustrated examples, of the invention has been presented only for the purpose of illustration and description and is not intended to be exhaustive or to limit the invention to the precise forms disclosed. Numerous modifications, adaptations, and uses thereof will be apparent to those skilled in the art without departing from the scope of this invention.

What is claimed is:

1. A supercapacitor device configured to be disposed in a wellbore through a fluid-producing formation, the supercapacitor device comprising:

a body configured to be disposed in the wellbore;

a supercapacitor disposed in the body and configured to store energy;

at least two terminals disposed at least partially outside the body, the at least two terminals configured to be electrically connected with the supercapacitor, wherein an electrical connection between the supercapacitor and the at least two terminals is adapted to cause the energy to be discharged from the supercapacitor in response to a conductive material providing an electrical path between the at least two terminals; and

an actuation mechanism configured to selectively prevent discharge of the energy from the supercapacitor when the supercapacitor device is deployed into the wellbore, wherein the actuation mechanism comprises:

a motor configured to selectively cause at least one terminal to be electrically disconnected from the supercapacitor; and

a control device configured to actuate the motor such that the at least one terminal is electrically connected to the supercapacitor.

2. The supercapacitor device of claim **1**, further comprising a control line coupled to a control unit at the surface of the wellbore, wherein the actuation mechanism is configured to be actuated by the control line such that the actuation mechanism allows the electrical path to be formed between the at least two terminals.

3. The supercapacitor device of claim **1**, wherein the control device is configured to actuate the motor in response to a control signal.

4. The supercapacitor device of claim **1**, wherein the control device comprises a force sensor configured to determine a depth of the supercapacitor device, wherein the control device is configured to actuate the motor in response to the depth exceeding a threshold depth.

5. The supercapacitor device of claim **1**, wherein the control device comprises a pressure sensor configured to determine a pressure in the wellbore, wherein the control device is configured to actuate the motor in response to the pressure exceeding a threshold pressure.

6. The supercapacitor device of claim **1**, further comprising at least one additional supercapacitor electrically connected in parallel with the supercapacitor, wherein the at least two terminals are further configured to be electrically connected with the supercapacitor and the at least one additional supercapacitor electrically connected in parallel.

7. The supercapacitor device of claim **1**, further comprising at least one additional supercapacitor electrically connected in series with the supercapacitor, wherein the at least two terminals are further configured to be electrically connected with the supercapacitor and the at least one additional supercapacitor electrically connected in series.

12

8. The supercapacitor device of claim **1**,

wherein the conductive material is coupled to a detonating material, the detonating material configured to detonate in response to an application of heat or a flow of an electrical current;

wherein the supercapacitor device is configured to provide the heat or the electrical current to the detonating material.

9. The supercapacitor device of claim **1**, wherein the at least two terminals are further configured to form the electrical connection with a battery in the wellbore, the battery comprising the conductive material, wherein the supercapacitor device is configured to charge the battery via the electrical connection.

10. The supercapacitor device of claim **1**, wherein the actuation mechanism further comprises at least one non-conductive material, the at least one non-conductive material adapted to surround at least one of the at least two terminals, wherein the actuation mechanism is further configured to selectively allow the electrical path to be formed between the at least two terminals by displacing the at least one non-conductive material.

11. A supercapacitor device configured to be disposed in a wellbore through a fluid-producing formation, the supercapacitor device comprising:

a body configured to be disposed in the wellbore;

a supercapacitor disposed in the body and configured to store energy;

at least two terminals disposed at least partially outside the body, the at least two terminals configured to be electrically connected with the supercapacitor, wherein an electrical connection between the supercapacitor and the at least two terminals is adapted to cause the energy to be discharged from the supercapacitor in response to a conductive material providing an electrical path between the at least two terminals; and

an actuation mechanism configured to selectively prevent discharge of the energy from the supercapacitor when the supercapacitor device is deployed into the wellbore, wherein the actuation mechanism comprises at least one non-conductive material, the at least one non-conductive material adapted to surround at least one terminal, wherein the actuation mechanism is configured to selectively allow the electrical path to be formed between the at least two terminals by displacing the at least one non-conductive material; and

a sensor configured to determine at least one of a depth of the supercapacitor device and a pressure in the wellbore, wherein the actuation mechanism is configured to selectively allow the electrical path to be formed between the at least two terminals in response to at least one of (i) the depth exceeding a threshold depth and (ii) the pressure exceeding a threshold pressure.

12. The supercapacitor device of claim **11**, wherein the actuation mechanism further comprises:

a motor configured to selectively cause at least one of the at least two terminals to be electrically disconnected from the supercapacitor; and

the control device configured to actuate the motor such that the at least one of the at least two terminals is electrically connected to the supercapacitor.

13. The supercapacitor device of claim **11**, further comprising at least one additional supercapacitor electrically connected in parallel with the supercapacitor, wherein the at least two terminals are further configured to be electrically connected with the supercapacitor and the at least one additional supercapacitor electrically connected in parallel.

13

14. The supercapacitor device of claim 11, further comprising at least one additional supercapacitor electrically connected in series with the supercapacitor, wherein the at least two terminals are further configured to be electrically connected with the supercapacitor and the at least one additional supercapacitor electrically connected in series. 5

15. The supercapacitor device of claim 11, wherein the conductive material is coupled to a detonating material, the detonating material configured to detonate in response to an application of heat or a flow of an electrical current; 10

wherein the supercapacitor device is configured to provide the heat or the electrical current to the detonating material.

16. The supercapacitor device of claim 11, wherein the at least two terminals are further configured to form the electrical connection with a battery in the wellbore, the battery comprising the conductive material, wherein the supercapacitor device is configured to charge the battery via the electrical connection. 15

17. A method comprising:

deploying a supercapacitor device in a wellbore through a fluid-producing formation, the supercapacitor device comprising:

a supercapacitor configured to store energy, 25
at least two terminals, and

an actuation mechanism configured to selectively prevent a deployment of the supercapacitor device in the wellbore from causing a discharge of the energy from the supercapacitor, wherein the actuation mechanism includes a motor that selectively causes at least one terminal to be disconnected from the supercapacitor; 30

14

positioning the supercapacitor device such that the at least two terminals are in contact with a conductive material in the wellbore;

discharging the energy from the supercapacitor by actuating the actuation mechanism, wherein actuating the actuation mechanism comprises electrically connecting the at least one terminal to the supercapacitor.

18. The method of claim 17, further comprising: melting the conductive material by discharging the energy from the supercapacitor;

coupling an object in the wellbore to the supercapacitor device via the conductive material; and

retrieving the supercapacitor device coupled to the object.

19. The method of claim 17, further comprising perforating an object in the wellbore by transferring heat to the object via the conductive material, wherein the heat is generated by discharging the energy from the supercapacitor.

20. The method of claim 17, further comprising coupling the conductive material to a detonating material configured to detonate in response to an application of heat or a flow of an electrical current, the detonating material configured to actuate a firing head assembly;

providing the heat or the electrical current to the conductive material by discharging the energy from the supercapacitor;

detonating the detonating material by providing the heat or the electrical current to the detonating material via the conductive material; and

perforating a tubing section in the wellbore by the firing head assembly.
